Abstract:

This paper investigates cream skimming behaviour by private hospitals via hospital transfers in a mixed public-private hospitals system. Previous work has shown that the likelihood of private-to-public transfers rises with patient complexity and severity. In contrast, the likelihood of public-to-private transfers tends to fall with patient complexity and severity. It has been argued that the observed pattern of transfers, although consistent with cream skimming, could also reflect the specialisation of private and public hospitals. This paper extends the previous work by examining the pattern of transfers when hospitals are faced with capacity pressure, which we argue is a plausible identification of cream skimming. Using Victorian hospital administrative data, we show that private hospitals tend to increase the transfer of complex and severe patients during times of capacity pressure (co-authored with Terence Cheng and Ou Yang).
